

## COURSE DESCRIPTION CARD - SYLLABUS

Course name

Medical informatics

### Course

Field of study

Computer science

Area of study (specialization)

Level of study

First-cycle studies

Form of study

part-time

Year/Semester

3/6

Profile of study

general academic

Course offered in

Polish

Requirements

elective

### Number of hours

Lecture

30

Laboratory classes

30

Other (e.g. online)

Tutorials

Projects/seminars

### Number of credit points

4

### Lecturers

Responsible for the course/lecturer:

Szymon Wilk, DSc, PhD, Eng

Responsible for the course/lecturer:

### Prerequisites

The student starting this course should have basic knowledge in information system architectures, databases, statistics and data analysis, artificial intelligence and physics.

The student should be able to design and implement (using selected tools and programming languages) simple information systems. They should also have the ability to obtain information from the indicated sources, as well as understand the need to expand their competences.

The student must present attitudes such as honesty, responsibility, perseverance, cognitive curiosity, creativity, personal culture, and respect for other people.

### Course objective

1. Provide students with basic knowledge in medical informatics, mainly related to medical data and methods of their acquisition (diagnostic devices), coding, standardization, storage (information systems), sharing, analysis (decision support) and presentation.

2. Present students with sample systems and programming tools used in medical informatics.

3. Develop students' skills in designing and implementing software created for the needs of applications related to the broadly understood health protection.
4. Develop students' ability to independently search and obtain information related to the design of IT solutions for medicine.

### Course-related learning outcomes

#### Knowledge

1. The student has organized and theoretically founded general knowledge on key issues of medical informatics.
2. The student has knowledge of important directions of development and achievements of medical informatics and other related scientific disciplines.
3. The student knows the basic techniques, methods and tools used in the process of solving tasks in medical informatics.

#### Skills

1. The student can obtain information related to medical informatics from various sources (publications, Internet resources), and properly integrate and interpret it.
2. The student is able to select appropriate methods, including simulation or experimental ones, when when formulating and solving tasks in medical informatics.
3. The student is able - following the provided specification - to design and implement a broadly understood medical information system, by selecting programming language appropriate to a given task and using suitable methods, techniques and tools.

#### Social competences

1. The student understands that in medical informatics knowledge and skills very quickly become outdated.
2. The student is aware of the importance of knowledge in solving problems in medical informatics and knows examples of malfunctioning medical systems or devices.

### Methods for verifying learning outcomes and assessment criteria

Learning outcomes presented above are verified as follows:

The knowledge acquired during the lecture is verified by a 45-minute test carried out during the last lecture, consisting of 10-15 questions (test and open), with diversified scores. Passing threshold: 50% of the total score. Topics, based on which the questions are developed, will be sent to students by university e-mail.

The skills acquired during the laboratory classes are verified through 2 projects with programming and experimental elements, implemented during the semester. The final grade is the average score for individual projects.

### Programme content

The first part of the lecture is devoted to the introduction and presentation of types of medical data, their sources and specificity. We also discuss integrated hospital information systems (HIS) and the more important medical standards used for encoding and transmitting non-image data, including HL7, SNOMED CT, LOINC, MeSH, and ICD, are discussed.

In the second part of the course, we present selected medical devices for laboratory, signal and imaging diagnostics. Within the first category we present devices for selected types of laboratory tests, as well as laboratory information systems (LIS) integrating laboratory diagnostic devices. The second category includes diagnostic devices generating multidimensional waveforms (EEG, ECG). We devote the most time to imaging diagnostic devices, both transmission and emission ones, including traditional X-ray diagnostics, computed tomography (CT) and nuclear magnetic resonance (MRI). We pay particular attention to modern techniques of functional imaging, especially fMRI or Doppler imaging (e.g., in combination with ultrasound or optical coherence tomography). Presentation of diagnostic devices is supplemented by a discussion of selected aspects of the processing and analysis of diagnostic data, algorithms used in these processes and the presentation of related standards and IT solutions, including picture archiving and communication systems (PACS), radiology information systems (RIS), and the DICOM (Digital Imaging and Communication in Medicine) standard.

The third part of the lecture is devoted to the application of advanced data analysis techniques in medicine, including artificial intelligence, machine learning and knowledge discovery. We present examples of clinical decision support systems, including mobile ones, as well as IT solutions for effective information retrieval, supporting the paradigm of evidence-based medicine.

Tentative plan of lectures:

- medical informatics - introduction; characteristics of medical data,
- hospital information systems,
- HL7, SNOMED CT, LOINC, ICD, MeSH standards,
- diagnostic devices - introduction and laboratory diagnostics,
- signal diagnostics: EEG, ECG,
- diagnostic imaging: X-ray, CT, MRI, fMRI,
- DICOM standard; PACS and RIS,
- supporting clinical decisions with the use of artificial intelligence and machine learning techniques (expert and learning systems),
- searching for information in clinical repositories,
- telemedicine and telemonitoring.

During the laboratory sessions, students individually or in groups of two prepare two mini-projects related to medical informatics. The projects are of practical nature and include the design, implementation and testing of simple systems implementing the indicated functionality. The list of currently proposed projects includes a CT simulator and a system for segmenting fundus images. This list is updated before the beginning of the semester according to the current state of the art in medical informatics. Students have two sessions to complete each project. Progress is checked during the

classes. The preparation of each project ends with a short presentation on the group forum, preparation of a short report describing the solution and handing over the source code to the instructor.

### Teaching methods

1. Lecture: multimedia presentation augmented with additional examples given on the whiteboard.
2. Laboratory exercises: preparation of small IT projects in groups of two or individually, multimedia presentation, demonstration.
